Superconductivity in LaRh₂Sn₂

Tuesday 08 Jul 2014 at 17:10 (01h50')

Abstract :

LaRh₂Sn₂ crystallizes in the centrosymmetric primitive tetragonal crystal structure $P4/mmm$ (number 123) [1] commonly referred to as the CaBe₂Ge₂-type which was confirmed on our synthesized samples by x-ray diffraction. The existence of this superconducting transition was published [2] and in this study we proceed with an extensive study into the properties of this superconducting ground state using physical property measurements. Electrical resistance and heat capacity measurements reveal a sharp and well defined superconducting transition $T_{SC} = 0.70 \pm 0.07$ K. The low-temperature heat capacity measurements show LaRh₂Sn₂ to be a weakly coupled [3] bulk BCS superconductor that has an s-wave singlet ground state with an isotropic energy gap 3.38 ± 0.06 meV. From the field dependence of the electrical resistance the upper critical field was estimated to be 0.127 ± 0.003 T. With the calculated penetration depth and coherence length LaRh₂Sn₂ is a type-II superconductor which was confirmed with low temperature magnetization measurements. reference [1] M. Award :

Yes

Level :

PhD

Supervisor :

Prof. A.M. Strydom, UJ

Paper :

Yes

Primary authors : Prof. STRYDOM, Andre (University of Johannesburg)

Co-authors : Mr. BRITZ, Douglas (University of Johannesburg)

Presenter : Mr. BRITZ, Douglas (University of Johannesburg)

Session classification : Poster1

Track classification : Track A - Division for Physics of Condensed Matter and Materials

Type : Poster Presentation
