Plastic scintillators form an integral part of particle detectors, such as the ATLAS detector at the LHC, as they are able to measure energies and track momenta of particles after a collision. Electron paramagnetic resonance (EPR) has been employed to study unpaired electrons and ions that are present in pristine and damaged plastic scintillator samples. Six different types of plastics were investigated, based on either polystyrene or polyvinyl toluene (PVT). Samples were subjected to irradiation doses between 0.8 – 80.0 MGy using 6 MeV protons. EPR studies conducted on these samples showed a decrease in g-factor of each sample with an increase dose. It is suggested that an increase in dose introduces secondary electrons and ions into the system increasing the spin density and the relaxation time. Computational DFT modeling of polystyrene and PVT monomers and dimers show that damaging the molecules decreases components of the g-tensor and alters the components of the hyperfine tensor related to the g-factor and relaxation time, respectively.

Apply to be
 considered for a student
 award (Yes / No)?

Yes

Level for award
 (Hons, MSc,
 PhD, N/A)?

MSc

Main supervisor (name and email)
and his / her institution

Prof. Bruce Mellado, Bruce.Mellado@Wits.ac.za, The University of the Witwatersrand
