Access to the Matjiesfontein Space Geodesy Observatory (MGO) is currently being compromised as the road is in a poor condition and intersects five drainage channels along the way. It is important that safe and reliable access be granted to the site as large, sensitive and expensive instruments need to be transported to site and for hauling material and machinery during construction. Once the observatory is functional, staff members and guest researchers will need to be able to drive to the site per normal light vehicle.

Low-level river crossings

Problem
There are currently no structures to allow for safe and reliable passage at any of the crossings and therefore low-level river crossings have to be designed for the first time as seen on the picture to the right. The crossings should ensure access to the MGO at all times, including the rainy season.

Method
The catchment areas that are contributing flow to each crossing were calculated and the mean annual precipitation for Matjiesfontein acquired. All catchment areas were smaller than 234 km², allowing the rational method to be used in order to estimate the peak flow at each crossing. A design factor is then applied to the peak flow to obtain the design flow. The flow capacity was calculated for a-grade and box-vented fords and should be greater than the respective design flow. Crossing 3 is larger than the other and necessitates the use of a vented ford, which has a greater capacity as seen in the table below.

<table>

Calculated design flow and flow capacity for each river crossing

Recommendations
From the hydraulic calculations, a-grade fords are recommended for crossing 1 and 3, and a boxed vented ford for crossing 2. Construction of the crossings should be carried out during dry season when the water level is low or preferably when it is dry. Due to the concrete having to cure for at least seven days, it is recommended that the construction team should start with crossing 3 and work back towards Matjiesfontein. This will enable the construction team to start working on crossing 3 without having to wait for the concrete slab of the first crossing to cure. The same applies for crossing 1.

The MGO Radio Telescope

The large instruments that need to be transported to site are the lunar laser ranger and radio telescope equipment, examples of which can be seen by the pictures to the left. As the MGO is to be an extension of the Hartbeespoort Radio Astronomy Observatory (HartRAO), it is only fitting that the observatory be equipped with its own radio telescope, which can be used to conduct geodetic very long baseline interferometry experiments among other. This technique allows scientists to determine the distances (baselines) between individual radio telescope antennas continuously, enabling continental drift to be measured. The telescope at HartRAO, shown on the right, moves at a rate of 2.5 cm per year in the north-east direction. Currently, two 30-cm diameter NAGA radio telescope antennas are expected to be installed at the MGO. Research is thus aimed at the successful installation of the structures from a geotechnical perspective.

Erosion repair of the access road

Problem
There is currently a basic existing dirt road which connects the town to the MGO, but its condition is not acceptable. Due to weathering and erosion, the road surface has degraded at a number of locations and renders difficulty of access to vehicles without any off-road capabilities.

Method
The access road was divided into three sections. A visual assessment of the road was done to establish the major issues within each section. From the graph above it is evident that erosive and longitudinal erosion are general problems, as well as excessive cutting in section 1 and transverse erosion in section 3. A total of 16 Dynamic Cone Penetrometers (DCP) tests were carried out in order to estimate the in-situ strength of the road material. After analyzing the results, the California Bearing Ratio (CBR) was calculated for each test. The graph below shows the best and worst results for each of the three road sections.

Recommendations
The material comprising the access road is overall very hard with bedrock often encountered near the surface. It is recommended however that the road surface be filled up and compacted as water is currently unable to escape the road and causes eroded material to wash away. Furthermore, side drainage should receive special attention.

Cornel Janse van Rensburg wishes to thank Carmen Behrens, Michael Klassen and his supervisor Leon Croukamp, as well as Inhaka yxAfrica for the opportunity to present this work.
