## 1. Introduction

This research quantitatively evaluates the natural radioactivity levels and geological radiation hazard parameters of soil and rock specimens obtained from mining locations in North-Eastern Nigeria, by means of gamma-ray spectroscopy. There have been potential public health risks associated with the use of soil and rock from mining locations in North-Eastern Nigeria, specifically the study areas. A total of twenty-eight samples were systematically gathered from Nahuta and Kashere locations. Through gamma spectrometry employing a NaI (TI) detector, the natural radioactivity levels of <sup>238</sup>U, <sup>232</sup>Th and <sup>40</sup>K were determined for each and every sample. The findings indicated that the mean activity concentrations of <sup>226</sup>Ra, <sup>232</sup>Th, and <sup>40</sup>K in Nahuta are  $46.13 \pm 4.78$  Bq/Kg,  $34.10 \pm 3.02$  Bq/Kg and  $473.94 \pm 5.41$  Bq/Kg for the soil samples respectively, and  $32.91 \pm 0.49$  Bq/Kg,  $40.70 \pm 0.41$  Bq/Kg, and  $578.18 \pm 4.28$  Bq/Kg for the rock samples respectively. The corresponding mean activity concentrations of <sup>226</sup>Ra, <sup>232</sup>Th, and <sup>40</sup>K in Kashere are  $17.99 \pm 4.18$  Bq/Kg,  $23.73 \pm 1.78$  Bq/Kg, and  $191.65 \pm 3.15$  Bq/Kg, for the soil samples, and  $20.24 \pm 3.72$  Bq/Kg,  $29.09 \pm 1.78$  Bq/Kg, and  $148.36 \pm 3.15$  Bq/Kg, for the rock samples respectively. An analysis of radiation risk parameters (D, AEDE, Raeq, Hex, Hin, AGDE and ELCR) has been conducted and findings explored. While the samples from the Kashere region fall within the international recommended levels, elevated readings of certain radiation health parameters are observed in the Nahuta region, posing serious public health risk due to utilization of the soil and rock from this area in construction activities.

## 1. Results

Larger activity concentration values for both soil and rock samples are found in Nahuta when compared with same for Kashere (Figure 1). In Nahuta, the ranges of radionuclide concentration for <sup>226</sup>Ra, <sup>232</sup>Th, and <sup>40</sup>K are  $16.20 \pm 4.26$  to  $53.94 \pm 4.72$  Bq/Kg with an average  $46.13 \pm 4.78$  Bq/Kg,  $13.02 \pm 3.32$  to  $62.71 \pm 4.37$  with an average  $34.10 \pm 3.02$  Bq/Kg and  $76.4 \pm 8.44$  to  $1126.53 \pm 8.90$  Bq/Kg with an average  $473.94 \pm 5.41$  Bq/Kg, respectively. Conversely, the radionuclide concentration of <sup>226</sup>Ra, <sup>232</sup>Th, and <sup>40</sup>K in Kashere ranges from  $17.99 \pm 4.18$  to  $29.56 \pm 8.91$  Bq/Kg with an average  $17.99 \pm 4.18$  Bq/Kg,  $14.60 \pm 0.47$  to  $34.60 \pm 0.71$  Bq/Kg with an average  $23.73 \pm 1.78$  Bq/Kg, and  $85.74 \pm 6.03$  to  $316.00 \pm 2.99$  Bq/Kg with an average  $191.65 \pm 3.15$  Bq/Kg, respectively. The activity concentration in rock samples is higher in Nahuta, with values for <sup>226</sup>Ra, <sup>232</sup>Th, and <sup>40</sup>K ranging from  $9.74 \pm 1.26$  to  $92.78 \pm 0.28$  Bq/Kg with an average  $32.91 \pm 0.49$  Bq/Kg,  $14.33 \pm 0.26$  to  $71.04 \pm 0.10$  Bq/Kg with an average  $40.70 \pm 0.41$ , and  $36.67 \pm 6.05$  to  $1136.50 \pm 5.54$  Bq/Kg with an average  $578.18 \pm 4.28$ , respectively. In Kashere, the ranges are  $11.07 \pm 8.91$  to  $38.06 \pm 0.17$  with an average  $20.24 \pm 3.72$  Bq/Kg for <sup>226</sup>Ra,  $13.47 \pm 6.23$  to  $42.43 \pm 0.36$  Bq/Kg with an average  $29.09 \pm 1.78$  Bq/Kg for <sup>232</sup>Th, and  $13.77 \pm 2.99$  to  $326.89 \pm 2.33$  Bq/Kg with an average  $148.36 \pm 3.15$  Bq/Kg for <sup>40</sup>K.

The concentrations of radionuclides <sup>226</sup>Ra, <sup>232</sup>Th, and <sup>40</sup>K in soil and rock samples, as reported by [1], average

at 32, 45, and 420 Bq/kg, respectively, worldwide. Analysis indicates that the average radionuclide concentration of  $^{226}\text{Ra}$ ,  $^{232}\text{Th}$ , and  $^{40}\text{K}$  in soil and rock samples from Kashere region are lower than the global averages, suggesting no imminent radiological threat to the local population. Conversely, the average activity concentration of  $^{226}\text{Ra}$  and  $^{40}\text{K}$  in soil and rock samples from Nahuta exceeds worldwide averages. These elevated levels are attributed to mining activities in the study area, which is abundant in natural radionuclides.

The calculated mean activity concentration of  $^{226}\text{Ra}$  is higher in the soil sample collected from Nahuta compared to Kashere. Nevertheless, compared to Nahuta, Kashere has slightly elevated levels in samples derived from rocks. This implies that the geological formation and mining exploration in Nahuta may have resulted in higher concentrations of radium than in Kashere where the rocks may contain higher concentrations of radium. The mean activity concentrations of  $^{232}\text{Th}$  in the soil and rock samples collected from Nahuta are higher than those obtained for Kashere. The higher thorium levels in Nahuta could be explained by the kind of rocks that compose the formations present in the area. The mean activity concentrations of  $^{40}\text{K}$  are higher in the soil and rock samples collected from Nahuta as compared to Kashere. Potassium-40 being present in many rocks occurs at higher concentrations in Nahuta, signifying a higher concentration of potassium bearing minerals in the area.

As observed in Figure 1, there are higher concentrations of  $^{226}\text{Ra}$ ,  $^{232}\text{Th}$ , and  $^{40}\text{K}$ , particularly in the soil samples obtained from Nahuta, which may pose a radiological health hazard to the inhabitants of the area. This is a health issue because prolonged exposure to these radionuclides contributes to cancer risk and other illnesses. Also, the sampled higher concentrations of these radionuclides suggest the need for environment management and monitoring systems, which should mitigate the impacts of mining and other agricultural activities. The results emphasize the necessity to follow the legal requirements concerning the radiation safety in the region with anthropogenic activities.

Fig. 1. Variation of the mean activity concentrations of  $^{226}\text{Ra}$ ,  $^{232}\text{Th}$ , and  $^{40}\text{K}$  given in Bq/Kg for Soil and Rock samples in the study locations.
