Abstract. A study of <sup>194</sup>Tl has revealed the presence of two strongly coupled negative-parity rotational bands up to the  $24^-$  and  $23^-$  states, respectively. These two bands are associated with the two-quasiparticle configuration at lower spins and the four-quasiparticle configuration at higher spins. The two 4-quasiparticle bands show exceptionally close near-degeneracy in the excitation energies. The relative excitation energies of these 4-quasiparticle bands were compared to the relative excitation energies of the best known chiral candidates with close near-degeneracy. This is one of the best cases of near degeneracy in partner bands observed to date, probably resulting from a chiral geometry in the angular momentum space. It is also the first pair of 4-quasiparticle bands associated with chiral symmetry.

#### 1. Introduction

The manifestation of chirality in atomic nuclei, originally suggested in Ref. [1] and vigorously investigated over the past few years from both the experimental and theoretical standpoint, continues to be the subject of intense discussion. Subsequent to the observation of chiral doublet bands in N = 75 isotones [2], candidate chiral bands have been reported in more than 21 nuclei in  $A \sim 80$ , 100, 130, 190 mass regions.

Nuclear chirality depends on a delicate balance between the collective core with a triaxial mass distribution and a single particle degree of freedom associated with a triaxial mass distribution and a single particle degree of freedom associated with the valence proton and neutron. An energy minimizing mechanism among the core and the valence nucleons results in a mutually perpendicular coupling of their respective angular momenta forming either a left- or right-handed system in the nuclear body-fixed frame. The intrinsic chirality then is seen in the laboratory frame, which is free of handedness, as a doubling of energy levels with the same spin and parity.

Figure 1. Partial level scheme showing the near-degenerate pair of rotational bands in <sup>194</sup>Tl. The uncertainties in the measured  $\gamma$ -ray energies are typically about 0.3 keV for most transitions, but increase to 0.5 keV for weak and doublet transitions.

Despite many discoveries reported on possible chiral partner bands, degenerate band structures are yet to be discovered, instant the currently known chiral candidates show similar properties rather than degeneracy. The best known nearly degenerate band structures were reported in odd- $A^{135}$ Nd [3],  $^{126,128}$ Cs [4, 5],  $^{104}$ Rh [6] and recently in  $^{194}$ Tl [7]. In the present report we discuss a candidate chiral band structure found in  $^{194}$ Tl and compare the observed degeneracies in the four nuclei  $^{135}$ Nd ,  $^{128}$ Cs and  $^{104}$ Rh.

## 2. Experimental method and Data analysis

High-spin states in <sup>194</sup>Tl were populated using the <sup>18</sup>O(<sup>181</sup>Ta, 5n) reaction at 93 and 91 MeV beam energies. The beam provided by the separator sector cyclotron (SSC) of the iThemba LABS impinged upon a self-supporting stack of two (and three) 0.5 mg/cm<sup>2</sup> target foils. The emitted  $\gamma$  rays were detected by the AFRODITE  $\gamma$ -ray spectrometer [8, 9], which comprised of 8 Compton-suppressed clover detectors and 6 LEPS detectors with the trigger logic set to accept events when at least two  $\gamma$  rays were detected in coincidence in the clover detector. The data were sorted into matrices and spectra and RadWare software package [10] was employed for analyses.

Figure 2. Comparison of the excitation energy vs spin plots of the best known close neardegenerate chiral candidate bands in <sup>194</sup>Tl, <sup>128</sup>Cs, <sup>135</sup>Nd and <sup>104</sup>Rh.

In order to determine the spins and parities of the new transitions angular distribution ratios,  $R_{AD}$ , and linear polarization anisotropies were measured, respectively. The previously known level schemes [11, 12] were revised and considerably extended. More than 130 new transitions were observed and placed in five rotational bands, three of which are observed for the first time. In this report we show the two bands which exhibit close-near-degeneracy, see Figure 1. Detailed experimental method and data analysis procedure for this experiment can be found in [7].

### 3. Results and Discussion

The properties of the partner bands in <sup>194</sup>Tl were evaluated with respect to the suggested fingerprints of chiral doublet bands such as: degeneracy in the excitation energies, moments of inertia, B(M1) and B(E2) reduced transition probabilities, and showed good similarities [7]. The remarkable feature of these two 4-quasiparticle  $\pi h_{9/2} \otimes \nu i_{13/2}^{-3}$  bands is the exceptionally good near-degeneracy observed in a long spin range.

Figure 2 presents the excitation energy as a function of spin for the partner bands in <sup>194</sup>Tl and in the previously known examples of partner bands with best near degeneracy, the twoquasiparticle  $\pi h_{11/2} \otimes \nu h_{11/2}^{-1}$  bands in <sup>126,128</sup>Cs (the near-degeneracy in <sup>126</sup>Cs is very similar to that in <sup>128</sup>Cs) and  $\pi g_{9/2}^{-1} \otimes \nu h_{11/2}$  bands in <sup>104</sup>Rh, and the three-quasiparticle  $\pi h_{11/2}^2 \otimes \nu h_{11/2}^{-1}$  bands in <sup>135</sup>Nd. The <sup>194</sup>Tl pair of four-quasiparticle bands maintain a constant relative energy

Figure 3. The difference in the excitation energies  $\Delta E$ , alignments  $\Delta i$ , and ratios of the reduced transition probabilities  $\Delta B(M1)/B(E2)$ , as a function of spin  $\Delta I$  with respect to the band head spin, for the 4-quasiparticle bands in <sup>194</sup>Tl, 3-quasiparticle bands in <sup>135</sup>Nd, and 2-quasiparticle bands in <sup>128</sup>Cs. The alignments are calculated with reference parameters of  $J_0 = 8 \hbar^2/\text{MeV}$  and  $J_1 = 40 \hbar^4/\text{MeV}^3$  for <sup>135</sup>Nd, and  $J_0 = 16 \hbar^2/\text{MeV}$  and  $J_1 = 33 \hbar^4/\text{MeV}^3$  for <sup>128</sup>Cs. Experimental data for <sup>135</sup>Nd and <sup>128</sup>Cs are taken from [3, 13] and [5], respectively.

separation of about 110 keV within the whole observed spin range of I = 19-23 and achieve a value as small as 37 keV at I = 21. The relative excitation energies of the levels in the <sup>126,128</sup>Cs partner bands remain approximately constant at  $\Delta E \sim 200$  keV over the whole observed spin ranges of I = 11-22 and I = 11-17, respectively while the relative excitation energy in the close near-degenerate bands of <sup>135</sup>Nd is not constant but decreases from  $\Delta E = 497$  keV at I = 22/2 and reaches a value of  $\Delta E = 94$  keV at I = 39/2 and a subsequent increasing trend is then observed. In the case of <sup>104</sup>Rh these partner bands also show a decreasing trend of the relative excitation energy from  $\Delta E = 413$  keV at I = 11, to an almost completely vanishing value of  $\Delta E = -1$  keV at I = 17.

The exceptional near-degeneracy of this pair of bands in <sup>194</sup>Tl is further illustrated in Figure 3 in which the differences in the excitation energies  $\Delta E = E_{side} - E_{yrast}$ , alignments  $\Delta i = i_{side} - i_{yrast}$ , and ratios of reduced transition probabilities  $\Delta B(M1)/B(E2) = B(M1)/B(E2)_{side} - E_{yrast}$   $B(M1)/B(E2)_{yrast}$  for the four-quasiparticle bands in <sup>194</sup>Tl and the partner bands in <sup>104</sup>Rh, <sup>135</sup>Nd, <sup>128</sup>Cs are shown. The spin  $\Delta I = I - I_0$  is with respect to the band head spin  $I_0$  of 9, 10, 25/2, and 18 are adopted for <sup>104</sup>Rh, <sup>128</sup>Cs, <sup>135</sup>Nd and <sup>194</sup>Tl, respectively.

In summary, the relative excitation energy of a pair of negative-parity bands observed in <sup>194</sup>Tl was compared to the relative excitation energies of the chiral candidates with best known close near-degeneracy. This comparison shows that near-degeneracy in the 4-quasipartcle bands in <sup>194</sup>Tl is possibly the best found to date.

### Acknowledgments

We would like to thank the crew of the iThemba LABS separated sector cyclotron for the delivery of the oxygen beam. This work is based upon research supported by the National Research Foundation, South Africa with grants GUN 65581 and 76632, and by a South Africa - Russian Federation bilateral agreement with a grant GUN 75248.
